S/Y Section: BSIT 3B
Course: WS1
Instructor: Rowell John Artiaga

Reflection:

1. Before Task 3, what happened when you searched for a show that doesn't exist, in sample mode and in live mode? Why didn't fetch report an error?

Before implementing Task 3 (Error Handling), searching for a non-existent show returned a 404 Not Found error in sample mode because the local JSON file did not exist, while in live mode, it returned an empty array ([]) from the TVmaze API. However, fetch did not report an error in these situations because it still considers the HTTP request itself successful (as long as the network connection to the server succeeds), meaning the response object's ok property can still be true even if no results were found.

2. Explain Promise.all in your own words. Why is it faster than three awaits in a row, and when would you not use it?

Promise.all() is a method in JavaScript used to execute and wait for multiple asynchronous operations concurrently such as fetching show details, cast, and seasons all at the same time. It is faster than three await statements in a row because it doesn't wait for one request to finish before starting the next; instead, it dispatches all network requests simultaneously. However, you should not use it if a subsequent request depends on the result of a previous one, or if you want other parts of your app to continue loading even if one request fails, because Promise.all immediately rejects if even a single promise fails.

3. Which bug took you the longest, and how did you find it (Console, Network tab, a classmate, an AI tool)?

The bug that took the longest to resolve was related to TypeError issues involving addEventListener and mismatches with HTML element IDs in JavaScript. I found this problem by inspecting the browser's *Console* tab, where I saw the red error messages pointing to null properties. With that information and the help of an *AI tool*, we were able to properly examine the code and correct the element IDs, such as aligning searchForm and query.
